1. Forward

The polarization dependence of backscatter is important in the design of radars. Studying this dependence can provide information about targets that is unobtainable with conventional radars. The University of Massachusetts Microwave Remote Sensing Laboratory has developed two high power millimeter-wave polarimetric radars, or polarimeters. These instruments, operating at 95 GHz and 225 GHz, were used to measure the polarimetric scattering properties of natural surfaces.

3. Body of Report

A. STATEMENT OF PROBLEM

There have been relatively few polarimetric backscatter studies performed at millimeter wavelengths. The University of Massachusetts has developed two radars, operating at 95 GHz and 225 GHz, to measure the polarimetric behavior of natural surfaces. Measurements taken with these polarimeters began in the summer of 1989, at 225 GHz. Within the next year we will have high power polarimeters operating at 35, 95 and 225 GHz. The results of measurements made to date are presented below.

B. RESULTS

Specifications of the 225 GHz polarimeter are shown in Table 1. This radar uses a noncoherent technique whereby the Mueller matrix of a target is measured by transmitting four or six polarizations sequentially. A comprehensive set of such measurements of trees was made, the results of which are detailed in [1] and [2]. Here we will summarize them. Eight species of trees were analyzed. Polarization signatures for Weeping Willow and White Pine trees are shown in Figures 1 and 2.

The 95 GHz polarimeter uses the coherent measurement technique to measure a target's polarimetric scattering matrix. This is then converted to a Mueller matrix for averaging. Specifications of this radar are shown in Table 2. Polarization signatures for White Pine and Weeping Willow are shown in Figures 3 and 4.

Co-Polarized Signature of Snow
at 225 GHz (75° Incidence)

Both radars were used to measure snow during the winter of 1990-91. The experiment consisted of mounting the instruments on a gantry on the edge of a building overlooking a snow field. Independent samples were obtained by moving the radars horizontally along the gantry while acquiring data. In-situ data were also obtained. Polarization signatures for snow at 95 and 225 GHz are shown in Figures 5 and 6. Measurements will continue for the winter 1991-92.

The depolarization ratio χ , is defined as

$$\chi \triangleq \frac{\sigma_{VH}^{\circ} + \sigma_{HV}^{\circ}}{\sigma_{VV}^{\circ} + \sigma_{HH}^{\circ}}$$

where σ_{ij} are the 4 co- and cross-pol backscatter coefficients. χ is a convenient parameter to compare among different tree types and snow conditions. A model has been developed that greatly simplifies the Mueller matrix by using χ as the single parameter [2]. The degree of polarization is described by

$$P_{\text{linear}} = \frac{1-\chi}{1+\chi}$$

for linear polarizations, and

$$P_{cp} = \frac{|1 - 3\chi|}{1 + \gamma}$$

for circular polarizations. A comparison of this model and data is shown in Figures 7 and 8.
